The Baylor Revision of the Motivation to Read Survey (B-MRS)

Marley W. Watkins and Larry J. Browning
Baylor University

Although reading motivation has been recognized as important by both teachers and researchers, scales to measure reading motivation have not been well validated. The structural validity of one promising measure of reading motivation, the Reading Survey (MRS) portion of the Motivation to Read Profile, was investigated in the current study with initial \( N = 933 \), calibration \( N = 545 \), and normative \( N = 2,146 \) samples. Data from the initial sample revealed the anticipated two factors of reading self-concept and value of reading, but identified three problematic items. Those items were replaced and the resulting Baylor revision of the MRS (B-MRS) was administered to the calibration sample. Exploratory factor analysis of the calibration sample data revealed the anticipated two factors with no problematic items. Confirmatory factor analysis was then applied to B-MRS data from the normative sample. Using multilevel methods because students were nested in classrooms, a two-factor theoretical structure was found to fit within students whereas a one-factor model best fit between classrooms.

Girls tended to have more positive reading self-concepts and valued reading at higher levels than boys while both reading self-concept and value of reading scores decreased as grade level increased. Norms were described and use of the B-MRS by practitioners and researchers was encouraged.

Keywords: factor analysis, validity, reading motivation, reading

The importance of reading to individuals and society cannot be overstated. Consequently, there is an obvious need to teach all children to read at proficient levels. Unfortunately, this need is not being effectively met. Data from the National Assessment of Educational Progress (NCES, 2013) indicates that 32% of tested 4th grade students and 22% of tested 8th grade students were Below Basic in reading skills. Below Basic means that these students did not demonstrate even partial mastery of the reading skills needed for proficient work at their grade level (NCES, 2013).

Reading skill and its development has been a major research interest in education and psychology for decades (Adams, 1990). Historically, most research focused on the cognitive aspects of reading such as phonemic awareness, word reading, fluency, vocabulary, and comprehension (Gough & Tunmer, 1986; LaBerge & Samuels, 1974; Perfetti & Stafura, 2014; Rayner, Foorman, Perfetti, Pesetsky, & Seidenberg, 2001; Snow, Burns, & Griffin, 1998). Stanovich (1986) noted that nearly every cognitive task that comprises the act of reading has been investigated, and more recent research has provided considerable guidance for fostering development of skilled readers (Hairrell, Rupley, & Simmons, 2011; Hattie, 2012; Hulme & Snowling, 2011; Marulis & Neuman, 2013; Piasta & Wagner, 2010; Slavin, Lake, Chambers, Cheung, & Davis, 2009; Snowling & Hulme, 2011).

Although important to teachers (O'Flahavan, Gambrell, Guthrie, Stahl, & Alvermann, 1992), aff-
Effects of teaching have only recently been recognized as potentially important contributors to reading proficiency (Afflerbach & Cho, 2011; Graham & Weiner, 1996; Hidi & Harackiewicz, 2000). Reading motivation in particular has garnered a substantial amount of attention as it applies to student learning (Graham & Weiner, 2012). For example, an early quantitative synthesis of the research on motivation and achievement found that around 11% of the variance in achievement was accounted for by motivation (Uguroglu & Walberg, 1979). More recently, a meta-analysis of 69 data sets involving more than 125,000 students found that verbal achievement and verbal self-concept were related at $r = .49$ (Möller, Pohlmann, Köller, & Marsh, 2009). These results seem to be consonant with commonsense views: It is intuitively pleasing to assume that students who read well do so partly because they are motivated to read, and those students who do not read well struggle partly because they are not motivated (Stanovich, 1986).

Over time, researchers have examined both affective and cognitive variables and considered the potential for interaction and synergy between cognitive skill and motivational will (Linnenbrink & Pintrich, 2002; Paris & Oka, 1986). In fact, considerable evidence has accumulated to suggest that affective and cognitive variables are reciprocally related and mutually reinforcing (Chamorro-Premuzic, Harlaar, Greven, & Plomin, 2010; Marsh, Xu, & Martin, 2012; Morgan & Fuchs, 2007; Retelsdorf, Köller, & Möller, 2014). Simultaneously, motivation theories (e.g., expectancy-value theory, self-determination theory, attribution theory, goal theory, etc.) were developed to explain the accumulating empirical findings and guide future research (Graham & Weiner, 2012; Pintrich & Schunk, 2002). These theories posit an array of constructs to explain motivated reading behavior (Anderman, Gray, & Chang, 2013; Guthrie & Coddington, 2009; Murphy & Alexander, 2000; Schiefele, Schaffner, Möller, & Wigfield, 2012), such as intrinsic and extrinsic motivation, perceived autonomy, self-concept, self-efficacy, task mastery goals, performance goals, prosocial goals, compliance goals, value, and autonomous motivation (Conradi, Jang, & McKenna, 2014).

As with all theories, those concerning reading motivation "can be divided into two parts: one that specifies relationships between theoretical constructs and another that describes relationships between constructs and measures" (Edwards & Bagozzi, 2000, p. 155). Most of the research on reading motivation has dealt with the relationships between theoretical constructs (i.e., reading motivation and reading achievement) and relatively little attention has focused on the relationship between constructs and measures. That is unfortunate because a robust construct-measure relationship allows an unambiguous mapping of theoretical constructs onto empirical measures and is, in effect, an auxiliary theory (Edwards & Bagozzi, 2000). In educational and psychological measurement, the construct-measure relationship is often recognized under the rubric of structural validity. That is, whether the structure of scores generated by a measure reflects the theoretical structure of the construct (Messick, 1995). Strong structural validity evidence facilitates both research and practice (Kane, 2013) and should precede research on the relationships between constructs (Meehl, 1990).

Recognizing a need for valid measures of reading motivation (Schunk, 2000), researchers have developed a number of scales designed to measure reading motivation, but most are distinguished by "poor construction and limited validation" (Fulmer & Frijters, 2009, p. 226). Two scales that have received considerable attention are the Motivations for Reading Questionnaire (MRQ; Wigfield, Guthrie, & McGough, 1996) and the Survey portion of the Motivation to Read Profile (MRS; Gambrell, Palmer, Codling, & Mazzoni, 1996). The MRQ is a 54-item group administered scale with a 4-point response format that purports to measure 11 aspects of reading motivation. Although the MRQ has frequently been applied in reading research (e.g., Klauda & Wigfield, 2012), an extensive analysis of its structural validity concluded that the MRQ should not be used (Watkins & Coffey, 2004, p. 117).

The MRS is a 20-item group administered survey with a 4-point response format that measures two aspects of reading motivation: self-concept as a reader and value of reading. An individually administered interview was also included in the Motivation to Read Profile but will not be considered further because it uses an open-ended question format and was not designed to be scored. Based on expectancy-value theory (Eccles, 1983), the items in the reading self-concept scale were designed to assess students’ expectations of success in reading and the items in

VALIDATION OF THE B-MRS

38
the value of reading scale were designed to measure the value students ascribe to reading. In essence, "Can I do it? Do I want it?" (Graham & Weiner, 2012, p. 372).

Structural validity for the MRS was supported by exploratory factor analysis (EFA) using unweighted least squares extraction and varimax rotation on data from 330 third- and fifth-grade students in 27 classrooms in four schools from two school districts in an Eastern state (Gambrell et al., 1996). Subsequently, the MRS has been applied in reading research (Applegate & Applegate, 2011; Gambrell, Hughes, Calvert, Malloy, & Igo, 2011; Marinak, 2013; Marinak & Gambrell, 2008, 2010; Quirk, Schwanenfugel, & Webb, 2009) and has twice been revised for use with adolescents (Kelley & Decker, 2009; Pitcher et al., 2007). Unfortunately, research on the MRS has not attended to its psychometric properties nor its structural validity.

The MRS was recently revised by Malloy, Marinak, Gambrell, and Mazzoni (2013) to modernize and update its content. The revised MRS retained seven of the original items, replaced one item, and modified 12 items. Modifications tended to be minor. For example, "almost never" replaced "not very often" as one response option and "My friends think reading is" replaced the original stem of "My best friends think reading is." The revised MRS was administered to 281 students in three schools in Virginia, South Carolina, and Pennsylvania. Alpha coefficients for the reading self-concept and value of reading scales were .81 and .85, respectively. It is not clear if the structural validity of the revised scale was evaluated because almost no methodological details were provided. For example, Malloy et al. (2013) simply reported that "a nonparametric analysis was used to determine validity using a root mean square error of approximation (RMSEA)...estimate of .089 was revealed" (p. 275). An RMSEA value of .089 would reflect a less-than-adequate overall fit of the model to the data, individual parameter estimates were evidently not reviewed, and there has been no other research on this revision of the MRS.

Critically, the structural validity investigations of the original MRS (Gambrell et al., 1996) and revised MRS (Malloy et al., 2013) were also methodologically flawed. For example, the four-option item responses constitute ordered categories rather than continuous values. In such cases, polychoric correlations should be submitted to factor analysis rather than Pearson product moment correlations (Flora, LaBrish, & Chalmers, 2012). Further, analyzing individual student data for classes of students violates the fundamental assumption of independence with an attendant risk of biased parameter estimates (De Naeghel & Van Keer, 2013; Muthén, 1994). Also, sub-dimensions of reading motivation (i.e., reading self-concept and reading value) are likely to be related to some extent and forcing them to be orthogonal with a varimax rotation as done by Gambrell et al. (1996) may have resulted in a distorted factor solution (Gorsuch, 1997). Finally, no other details of the factor analyses were reported by Gambrell et al. (1996) or Malloy et al. (2013), which does not allow for informed review and replication (Ford, MacCallum, & Tait, 1986).

Given these lacunae, the current study was designed to analyze the structural validity of the original MRS and use that evidence to revise the MRS and collect validity evidence on the new revision. The resulting validity evidence will allow practitioners to better identify, implement, and evaluate interventions to improve reading motivation and achievement (Guthrie, 2011) and will provide researchers with a measure for use in future research.

Original MRS Study

Method

Instrument. The Reading Survey portion of the Motivation to Read Profile is a 20-item (each with four response options) scale for students in grades 2-6. As described by Gambrell et al. (1996), it is a "public-domain instrument" (p. 519) with 10 reading self-concept items "designed to elicit information about students' self-perceived competence in reading and self-perceived performance relative to peers" and 10 value of reading items "designed to elicit information about the value students place on reading tasks and activities" (p. 522).

The first validation study by Gambrell et al. (1996) included 330 third- and fifth-grade students in 27 classrooms in four schools from two school districts in an Eastern state. Gambrell et al. (1996) found that internal consistency reliability was .75 and .82 for the self-concept and value scales, respectively. An alpha coefficient of .89 was subsequently compu-
Participants. A total of 933 students (48.8% male) in grades 1 through 5 (5.5% in first grade with 55% male, 7.5% in second grade with 54% male, 30% in third grade with 48% male, 32% in fourth grade with 45% male, and 25% in fifth grade with 52% male) from Arizona \( (n = 340) \), Maryland \( (n = 333) \), and Pennsylvania \( (n = 260) \) completed all 20 MRS items. No further demographic information was collected on individual students to protect participants’ confidentiality.

Procedures. Data were obtained from elementary schools in Arizona \( (n = 1) \), Maryland \( (n = 2) \), and Pennsylvania \( (n = 1) \) secondary to other research projects or local program evaluations (Neuhard, 2004; Runge, 1998; Young, 2000). Students were enrolled in 42 separate classrooms with an average class size of 22.2 students. The Pennsylvania school was located in a rural area, fewer than 1% of its students were minority, and around 35% of its students received free or reduced lunch. The Maryland schools were in suburban areas, around 28% of their students were minority and 43% received free or reduced lunch. The Arizona school was also in a suburban area. Around 25% of its students were minority and around 30% received free or reduced lunch. Directions and test items were read aloud to students by researchers or teachers following the instructions provided by Gambrell et al. (1996). Unit weighted reading self-concept and value of reading scores were computed as per Gambrell et al. (1996).

Analyses. Given the well-developed theoretical expectation of two MRS factors, confirmatory factor analysis (CFA) was implemented with Mplus version 7.2 (Muthén & Muthén, 2014). Based on the ordered categorical data, polychoric correlations and the WLSMV estimator were selected (Lei & Wu, 2012). Overall model fit was evaluated with the comparative fit index (CFI) and the root mean square error of approximation (RMSEA). Criteria for adequate model fit were CFI ≥ .90 and RMSEA ≤ .08 whereas good model fit required CFI ≥ .95 and RMSEA ≤ .06 (Hu & Bentler, 1999). Intraclass correlations for items ranged from .03 to .08 with a median of .06, indicating that non-independence of student data should be considered in the analyses (Muthén, 1997).

Results

As suggested by Hox (1995), a baseline model was established by comparing one- and two-factor models without regard for nested data. The two-factor model was clearly superior to the one-factor model (CFI of .95 vs .83 and RMSEA of .07 vs .14, respectively) although its overall fit was only adequate. Next, the non-independence of student data was taken into account with the Mplus cluster procedure in a two-factor model, which exhibited good fit to the data (CFI of .96 and RMSEA = .05). Thus, the two-factor structure of the Reading Survey portion of the Motivation to Read Profile was supported. The two factors correlated at .60 and exhibited alpha coefficients of .82 (95% CI [.78, .85]) for the reading self-concept factor and .84 (95% CI [.80, .87]) for the value of reading factor.

Regardless of overall model fit, inspection of the standardized parameter estimates revealed two problems with the two-factor model: one reading self-concept item (#11) and one value of reading item (#18) were weakly related to their respective factors (.12 and .21, respectively) in comparison to the remainder of the items \( (Md = .70) \). Additionally, several students spontaneously wrote critical comments on protocols about the stem of item 17 \( (\text{When I am in a group talking about stories}) \) indicating that talking about stories in a group was only for primary grade students. Interestingly, the lack of ecological validity of item #17 may have been noticed in prior studies because its stem was revised in both attempts to create an adolescent version of the MRS (i.e., Kelley & Decker, 2009; Pitcher et al., 2007). Altogether, then, three of the 20 items on the Survey portion of the Motivation to Read Profile were problematic and required revision or replacement.

Results for the reading self-concept and value of reading scales across grade level and sex are illustrated in Figure 1. Regression analyses were conducted using clustered robust standard errors within Stata 13 to adjust for non-independence of the data. For reading self-concept, grade was a statistically significant predictor \( (t = -2.47, df = 4, p = .018, R^2 = .02) \), but neither sex nor the grade by sex interaction were significant predictors \( (p > .05) \). In contrast, both grade \( (t = -4.10, df = 4, p < .001, R^2 = .06) \) and sex \( (t = 2.61, df = 1, p = .013, R^2 = .02) \) were significant.
predictors for the value of reading scale, but the grade by sex interaction was not a significant predictor \( (p > .05) \). The correlation between grade and reading self-concept was -0.10 and between grade and the value of reading was -0.23 indicating that both types of reading motivation declined as grade level increased. The correlation between sex and the value of reading was 0.13, indicating that girls tended to value reading more than boys.

**Calibration Study**

**Method**

**Instrument.** Seventeen items of the Reading Survey portion of the Motivation to Read Profile were retained. Several alternatives were created for items 11, 17, and 18 and qualitatively reviewed by a reading expert and a psychometrician. Following pilot tests with small samples of volunteer students, new items 11, 17, and 18 were selected based on psychometric performance and incorporated into the Baylor revision of the MRS (B-MRS). The B-MRS scale as well as standardized administration instructions and score sheets can be freely downloaded from [http://edpsychassociates.com](http://edpsychassociates.com).

**Participants.** A total of 545 students (49.5% male) in grades 1 through 8 (10% in first grade with 48% male, 17% in second grade with 48% male, 17% in third grade with 45% male, 15% in fourth grade with 56% male, 15% in fifth grade with 51% male, 3% in sixth grade with 66% male, 18% in seventh grade with 45% male, and 5% in eighth grade with 56% male) served as participants. No further demographic information was collected on individual students to protect participants' confidentiality.

**Procedures.** Data were obtained from a school in rural Pennsylvania secondary to local program evaluation activities. No further identifying information about students or teachers was made available. However, the school district enrolled around 9% minority students and offered free/reduced lunch to approximately 57% of its students. Directions and test items were read aloud to students by teachers following standardized instructions.

**Analyses.** Given the scale revision and attendant

---

*Figure 1. Reading Self-Concept and Value of Reading Scores on the Motivation to Read Survey (MRS) for 933 Male and Female Students in Grades 1 Through 5.*
uncertainty about its structure, an EFA using poly-
choric correlations was applied with the psych pack-
age within the R program (R Development Core Team, 2014). Following the best practice EFA guide-
lines (Ford et al., 1986; Gorsuch, 1997), the number of factors to retain for rotation was determined by parallel analysis and minimal average partials (MAP) criteria, principal axis extraction with obli-
min rotation were specified, and pattern coefficients ≥ .32 were predetermined to be salient.

Results

Both parallel analysis and MAP criteria indicated that two factors should be extracted. Three factors were extracted as a deliberate over-extraction strategy. As expected, the resulting third factor was inad-
equate, being loaded by six items of which four were complex, leaving only two items to uniquely identify the third factor. In contrast, the two-factor solution clearly identified ten items for each factor (see Table 1). Internal consistency reliability was strong, .84 (95% CI [.80, .87]) for the reading self-concept fac-
tor and .87 (95% CI [.84, .90]) for the value of reading factor.

Results for the reading self-concept and value of reading scales across grade level and sex are illus-
trated in Figure 2. There were too few students in several cells for a valid test across grade levels, but the correlation between grade and reading self-concept was -0.07 and between grade and the value of reading was -0.36. Thus, reading motivation decreased as grade level increased. Additionally, males and females did not significantly differ on the reading self-concept scale ($t = 0.59$, $df = 531$, $p = .56$, $R^2 < .01$) but were statistically different in favor of females on the value of reading scale ($t = 4.29$, $df = 531$, $p < .001$, $R^2 = .04$).

Normative Study

Method

Instrument. Given the clear factor structure found in the calibration study, B-MRS data were col-
lected and analyzed in a validation study.

Participants. A total of 2,136 Texas students (52% male) in grades 2 through 6 served as partici-
pants. By grade level, there were 301 students (53% male) in grade 2, 269 students (54% male) in grade 3, 372 students (49% male) in grade 4, 588 students (51% male) in grade 5, and 606 students (53% male) in grade 6. No further demographic information on individual students was collected to protect participants' confidentiality.

Procedures. The names and work addresses of 1,000 randomly selected Texas teachers in grades 2-
6 were purchased from a commercial marketing firm. Those 1,000 teachers were solicited via U.S. Mail to anonymously collect and share B-MRS data from their classrooms. Each solicitation letter contained a classroom supply of B-MRS forms and standardized instructions for data collection. Responses were re-
ceived from 88 teachers who provided B-MRS data for 2,371 students in grades 1-8. The data of 2,136 students in 83 grade 2-6 classrooms who completed all 20 B-MRS items were retained for the validation study.

Analyses. Given theory and results of the cali-
bration study, CFA was implemented with Mplus version 7.2 (Muthén & Muthén, 2014). Based on the ordered categorical data, polychoric correlations and the WLSMV estimator were selected (Lei & Wu, 2012). Overall model fit was evaluated with the CFI and RMSEA. Criteria for adequate model fit were CFI ≥ .90 and RMSEA ≤ .08 whereas good model fit was set at CFI ≥ 0.95 and RMSEA ≤ 0.06 (Hu & Bentler, 1999). Intraclass correlations for items ranged from .05 to .21 with a median of .09 indicating that non-independence of student data should be considered in the analyses (Muthén, 1997).

Results

A baseline model was established by comparing one- and two-factor within-student models without regard for nested data (Hox, 1995). The two-factor model was clearly superior to the one-factor model (see Table 2) although its overall fit was only ade-
quate. Consequently, multilevel models with two within-student and one and two between-classroom factors were analyzed. All multilevel models exhib-
ited good fit to the data but four residual item vari-
ances were negative in the model with two between-
classroom factors, making that model inadmissible. Fewer factors are often found at the between level of multilevel models (Brown, 2013) so this result was not unusual. Thus, the two within-student and one
between-classroom factor model was the best fit to the data and is illustrated in Figure 4. Alpha coefficients for the reading self-concept and value of reading scales were both .87 with 95% CIs [.85, .89].

Reading self-concept and value of reading scores across grade level and sex are illustrated in Figure 3. Regression analyses were conducted using clustered robust standard errors within Stata 13 to adjust for non-independence of the data. For the reading self-concept scale, neither grade, sex, nor the grade by sex interaction were significant predictors \((p > .05)\) with all three predictors combined accounting for less than 2% of the variance in reading self-concept. In contrast, both grade \((t = -5.55, df = 4, p < .001, R^2 = .11)\) and sex \((t = 1.96, df = 1, p = .054, R^2 = .03)\), but not the interaction of grade and sex \((p > .05)\), were significant predictors of the value of reading scale. The correlation between grade and the value of reading was -0.32 indicating that the perceived value of reading declined as grade level increased. The correlation between sex and the value of reading was 0.16, indicating that girls tended to place higher value on reading than boys.

**Norms.** The original MRS lacks a representative normative sample, which is a "minimal requirement for using a test for diagnostic purposes" (Bear, Minke, & Manning, 2002, p. 423). Without a standardized, normative comparison, MRS scores are essentially uninterpretable for clinical use and do not allow advances in research on reading motivation. The lack of norms was seen as a specific weakness of the MRS by Fulmer and Frijters (2009), and other researchers have recommended the development of norms for the MRS (Kelley & Decker, 2009).

Figure 4. Multilevel structural model of the validation sample of 2,136 Texas students on the 20 items that comprise the Baylor Revision of the Motivation to Read Survey (B-MRS). Motivate is General Reading Motivation, Self-Con is Reading Self-Concept, and Value is Value of Reading.
Texas norms for the B-MRS were developed with the validation sample based on unit weighted raw scores (Bobko, Roth, & Buster, 2007; Wainer, 1976) and percentiles for their simplicity (Salvia, Ysseldyke, & Bolt, 2010). Given the unequal number of males and females at each grade level, students' scores were weighted to achieve an overall sample size of 1,500 with 150 boys and 150 girls at each of the five grade levels. Separate norms tables were created for each grade level due to the major influence of grade level, especially on the value of reading scale. Norms tables as well as the B-MRS scale, standardized administration instructions, and score sheets can be freely downloaded from http://edpsychassociates.com.

Discussion

Although reading motivation has been recognized as important by both teachers and researchers, scales to measure reading motivation have, unfortunately, been of "poor construction and limited validation" (Fulmer & Frijters, 2009, p. 226). The structural validity of one promising measure of reading motivation, the Reading Survey (MRS) portion of the Motivation to Read Profile was investigated in the current study. Based on that initial investigation, the MRS was revised and its psychometric properties and structural validity examined in calibration and normative samples. The revised scale was found to measure two related \( r = .58 \) reading motivation factors within students (reading self-concept and value of reading), both with good reliability \( \alpha = .87 \), and one factor between classrooms. Thus, it appeared that students differentiated the value of reading from reading self-concept, and teachers unitarily influenced both facets of reading motivation (De Naeghel & Van Keer, 2013).

Female students in grades 2-6 exhibited more positive reading self-concept and value of reading scores than did male students. However, the male-female differences were small for both reading self-concept (less than 1% of variance) and value of reading (3% of the variance). Grade level accounted for less than 1% of the variance in reading self-concept but for 11% of the variance in the value of reading scale. Previous research with the MRS found similar patterns of scores by sex and grade level. That is, girls have tended to have a more positive reading self-concept and to value reading more than boys while both reading self-concept and value of reading scores decreased as grade level increased (Archambault, Eccles, & Vida, 2010; Applegate & Applegate, 2011; Gambrell et al., 2011; Marinak & Gambrell, 2010; Retelsdorf, Schwartz, & Asbrock, 2014). Reading attitudes have also been found to be more positive for girls than boys and to decrease across grade levels (Kush & Watkins, 1996; McKenna, Conradi, Lawrence, Jang, & Meyer, 2012; McKenna, Kear, & Ellsworth, 1995). Thus, these affective patterns appear to be robust phenomena.

Strong structural validity evidence facilitates both research and practice (Kane, 2013) and should precede research on the relationships between constructs (Meehl, 1990). The current studies have provided strong structural validity evidence for the B-MRS. Thus, research on the relationship of reading self-concept and the value of reading with other theoretical constructs (e.g., reading achievement, reading attitudes, etc.) can now be conducted with these subscales serving as marker variables (Gorsuch, 1988).

Limitations

The biggest limitations of these studies were use of samples of convenience as well as the low response rate of Texas teachers with the resulting inability to judge the representativeness of the normative sample. Although 1,000 Texas teachers were randomly sampled, only 88 responded with B-MRS data from their classrooms. It is possible that the classrooms of these respondents were somehow non-representative. Additionally, lack of demographic information about individual participants makes it impossible to know if the students in the norm sample were representative of the state. Although validity may not be impacted by convenience samples (Mullinix, Druckman, & Freese, 2014), it would be advisable for users to supplement the B-MRS Texas norms with local norms.

Implications for Practice

It is widely accepted that motivation is involved in students' reading development (Afflerbach, Cho, Kim, Crassas, & Doyle, 2013), that reading failure has negative affective correlates (Morgan, Farkas, & Wu, 2012), and that interventions to improve reading
motivation and achievement may be most effective for younger children (Retelsdorf, Köller, & Möller, 2014). Fortunately, investigators (e.g., Baker, Scher, & Mackler, 1997; Edmunds & Bauserman, 2006; Guthrie et al., 2006; Malloy, Marinak, & Gambrell, 2010; Marinak, 2013; McRae & Guthrie, 2009; Mece & Miller, 1999; Monteiro, 2013; Wentzel & Wigfield, 2007; Wigfield, Guthrie, Tonks, & Perencevich, 2004) have identified home and school practices that improve student motivation to read. Several promising school practices were identified by Marinak (2013) who found that fifth grade teachers who offered structured read alouds, cooperative learning via jigsaws, and book club choices improved the perceived value of reading to their students. Other promising school interventions include cross-age peer tutoring, which has improved the reading motivation of both tutors and tutees (Monteiro, 2013) and the concept-oriented reading instruction program (Guthrie, McRae, & Klauda, 2007) that combines reading instruction with support for student motivation. Home practices that have been shown to improve reading motivation include shared storybook reading (Bus, van Ijzendoorn, & Pellegrini, 1995) and other family literacy activities that fostered active parent-child engagement (Yeo, Ong, & Ng, 2014). The B-RMS is a tool that teachers may now systematically apply (e.g., as described by Malloy et al., 2013) to target and monitor interventions that affect reading motivation, knowing that it has exhibited strong evidence of reliability and validity.
